ABSTRACT

Disclosed is a filing tool for hardened-skin care, including a plurality of filing parts having double plated nickel and stone powders fixed to such nickel on a metal plate. A method of manufacturing the filing tool is also provided, including setting a patterned photosensitive dry film on the metal plate, exposing the metal plate set with the dry film to light, removing a non-exposed portion of the dry film to form a masking pattern, plating nickel on the metal plate formed with the masking pattern to form a first nickel-plated layer, followed by uniformly applying stone powders on the first nickel-plated layer, further plating nickel on the stone powders to form a second nickel-plated layer, and fixing the stone powders between the first nickel-plated layer and the second nickel-plated layer, followed by removing the masking pattern. Thereby, since a filing material, the stone powders, serving as are securely fixed to nickel, filing efficiencies improve. addition, the filing tool has higher strength, due to the use of the metal plate.
